Albumin is a 65-70 kDa protein. Albumin comprises three homologous domains that assemble to form a heart-shaped protein. Each domain is a product of two subdomains that possess common structural motifs. The principal regions of ligand binding to human serum albumin are located in hydrophobic cavities in subdomains IIA and IIIA, which exhibit similar chemistry. Structurally, the serum albumins are similar, each domain containing five or six internal disulfide bonds.

Albumin - Wikipedia

Albumin is synthesized by the hepatocyte. It finds its way directly into the hepatic plasma and, hence, to the systemic circulation. Its half-time of survival is 20 days in man, and it is degraded in sites yet unknown. The most important factor regulating albumin synthesis is nutrition.

Your liver is responsible for filtering proteins in the blood and breaking the proteins down into smaller molecules for use. The liver then uses these proteins to create albumin, which is then circulated through the body. To maintain normal blood albumin ranges, you should have between 3.4 and 5.4 g/dL of albumin in your blood.

Role of Albumin | Healthfully

Albumin transports hormones, fatty acids, and other compounds, buffers pH, and maintains oncotic pressure, among other functions. Albumin is synthesized in the liver as preproalbumin, which has an N-terminal peptide that is removed before the nascent protein is released from the rough endoplasmic reticulum.

Human serum albumin - Wikipedia

What Albumin Does and How It Functions Albumin maintains the osmotic pressure that pulls water into the circulatory system. The pressure inside blood vessels exerted by pumping of the heart (hydrostatic pressure) creates a force to push fluids out of veins and arteries into the surrounding tissue.
