CHEMISTRY AND TECHNOLOGY OF ISOCYANATES

Isocyanates, especially diisocyanates and polyisocyanates, are important monomers that undergo a broad range of chemical reactions. For example, they can react with compounds containing active hydrogen atoms, like amines, alcohols, mercaptanes, water, and carboxylic acids or they can react with themselves to form dimers (uretdiones) and trimers (isocyanurates) or they can be polymerized to polyisocyanates (N-substituted 1-nylons).

Isocyanate Reactions

Isocyanate is the functional group with the formula R–N=C=O. Organic compounds that contain an isocyanate group are referred to as isocyanates. An organic compound with two isocyanate groups is known as a diisocyanate. Diisocyanates are manufactured for the production of polyurethanes, a class of polymers.

Isocyanates used to make polyurethane have two or more isocyanate groups on each molecule. The most commonly used isocyanates are the aromaticdiisocyanates, toluene diisocyanate(TDI) and methylene diphenyl diisocyanate, MDI. TDI and MDI are generally less expensive and more reactive than other isocyanates.

Polyurethane - Wikipedia

The most common forms of isocyanates are toluene diisocyanate (TDI), methylene diphenyl diisocyanate (MDI) and hexamethylene diisocyanate (HDI). TDI is a liquid at room temperature, and can cause asthma-like conditions when inhaled as an aerosol. TDI is a key ingredient in many spray paints and coatings.

Isocyanates in general are highly reactive to compounds that contain an active hydrogen group(s) and therefore, to allow meaningful workplace measurements to be made, methods used for monitoring airborne concentrations must be capable of trapping and derivitizing the isocyanate(s) to a stable derivative(s) in-situ.
